Developing test questions based on STACK plugin in ILIAS

Dr. Sameer Arabasi School of Basic Sciences and Humanities German Jordanian University Host Partner: Dr. Thomas Risse Hochschule Bremen

Introduction and Motivation:

ILIAS (Integriertes Lern-, Informations- und Arbeitskooperations-System (German for "Integrated Learning, Information and Work Cooperation System")) is a web-based open source Learning Management System (LMS). Learning management systems have become a standard in modern educational institutions as they offer content management, cooperation, assessment and evaluation [1]. GJU uses a different LMS called MOODLE. STACK (System for Teaching and Assessment using a Computer algebra Kernel) is a plugin that provides a type of mathematical test questions that are calculated by a Computer Algebra System (CAS) called MAXIMA. It has the many features and advantages such as [2]:

- Different question versions are randomly generated.
- There are many different kinds of inputs. Input could be, for example, a mathematical expression, or a simple true/false selection.
- Mathematical properties of students' answers are established using answer tests within the CAS Maxima.
- Feedback is assigned on the basis of these properties using a potential response tree.
- Generates outcomes which fulfill the purpose of formative, summative and evaluative assessment
- Stores data on all attempts at a certain question and/or by a certain student to be analyzed by the teacher.
- Multi-part mathematical questions are possible: each question may have any number of inputs and any number of potential response trees.
- Partial credit is possible when an expression only satisfies some of the required properties.
- Plots can be dynamically generated and included within any part of the question, including feedback in the form of a plot of the student's expression.

Goals and timeline:

At the beginning of my visit to Hochschule Bremen(HSB), the collaborating partners listed the following goals to be achieved:

- Get familiar with ILIAS and its features and capabilities. (First week)
- Start authoring quizzes and exams and explore the possibility of having the math placement test at GJU done via ILIAS. (First week)
- Get familiar with MAXIMA, the computer algebra system in which STACK operates. (First and Second week)
- Get familiar with STACK and seek a platform where it could be installed and used. (Second week)
- Develop tests on ILIAS with STACK using different types of questions. (Third and Fourth week)
- Discuss the possibility of setting up the system on GJU servers. (Second week)
- Discuss the possibility of having questions for different courses at GJU in both English and German so that the students get familiar with the technical terms in both languages. (Third and Fourth week)

The vision is to have a weekly or bi-weekly homework assignments for all the first-year courses. These assignments will contain some questions fully in German. Students can seek help from their instructor who will be given an English translation of the question or they could ask their German instructors to translate some of the vocabulary in the question. This way the students will learn their technical vocabulary early on and gradually in contrast to taking it all at once in advanced German courses. This goal requires collaborations between GJU and HSB to author the questions in German and help GJU instructors to understand these questions. GJU instructors could author the questions and ask for a translation by HSB instructors or German language instructors here at GJU.

ILIAS has been used at HSB for quite some time. They are very familiar with the system and has been used to give exercises and sample exams. I would like to look into the opportunity of having the math placement tests at GJU done via ILIAS. Our technical IT team will need some training which could be provided by Mr. Ralf-Peter Balke of HSB who kindly agreed to help in any technical details needed.

Future work:

This project is to continue after my return to Jordan. Collaboration will continue between Dr. Thomas Risse and myself. We will discuss the progress during his visit to GJU in November.

Acknowledgements and Concluding remarks:

I would like to thank the DAAD for providing the financial support which made this collaboration possible through Train-the-Trainer program. I would like also to thank my host Dr. Risse at Hochschule Bremen for his generous hospitality and volunteering his precious time to work on this project under his guidance.

Examples:

I will show two examples of questions written in ILIAS using the STACK plugin:

The first one is a Physics question in Mechanics and the second one is a Mathematics question in Differential Equations.

The first example shows the power of ILIAS and specifically when using STACK and its CAS MAXIAMA in generating multiple versions of the same question and solving the quadratic equation which represents the problem for each version.

AULIS Hochschule Bremen	PERSONAL DESKTOP + REPOSITORY + A stone is thrown from the top of a building with an initial velocity of 40 m/s downward. The top of the building is 60 m above the ground. The second example is more elaborate and shows the STACK advantage in designing specific feedbacks for every student answer and its capability in understanding the student answers when the answer is a mathematical expression.

Solving a second order ODE:

We will solve a second-order ODE when the roots of the characteristic equation are complex numbers.

Here we will use the potential response tree to provide feedback for the student. The purpose of STACK is to assess students' answers to mathematical questions, and on the basis of the properties we establish to assign feedback.

- Formative assessment is to support and inform students' learning. Feedback here could be qualitative, e.g. written comments tailored to the student's answer and designed to help them improve their performance on the task.
- Summative assessment is to establish the achievement of the student. In mathematics, summative feedback is most often quantitative, either a mark or a percentage.
- Evaluative assessment is to measure the effectiveness of the teaching or the assessment of students. Such assessments could have quality enhancement or quality audit functions

Here is the question and the correct responses. The instructor could also insert a figure to show the student how the answer looks like when plotted.

Question variables:

Potential Response Tree:

The potential response tree is the algorithm which establishes the mathematical properties of the student's answer and assigns outcomes.

Each potential response tree can set Maxima's level of simplification. Before the tree is traversed the feedback variables are evaluated. The feedback variables may depend on the values of the question variables and the inputs. The values of these variables are available to the answer tests and all CASText fields within the tree, for example the feedback could be built using these variables.

A potential response tree consists of one or more nodes that are linked together. In each node two expressions are compared using a specified answer tests, and the result is either true or false. A corresponding branch of the tree can do the following:

- Adjust the score, (positive or negative).
- Add written feedback specifically for the student
- Generate an "answer note", used by the teacher for evaluative assessment
- Nominate the next node, or end the process.

The outcomes are:

- The raw score
- The penalty for this attempt
- Feedback to the student
- An Answer Note

The potential response tree itself is expected to return a numerical raw score between 0 and 1. This number is multiplied by the question value before being returned to the student as feedback or recorded in the database [2].

In our last example, we have four parts and hence four potential response trees. Here is how they were programmed.
